Chapter 12
Inventory Management

Outline

- Global Company Profile: Amazon.Com
- Functions Of Inventory
  - Types of Inventory
- Inventory Management
  - ABC Analysis
  - Record Accuracy
  - Cycle Counting
  - Control of Service Inventories
Outline – Continued

☑ Inventory Models
  ☑ Independent versus Dependent Demand
  ☑ Holding, Ordering, and Setup Costs

Outline – Continued

☑ Inventory Models For Independent Demand
  ☑ Basic Economic Order Quantity (EOQ) Model
  ☑ Minimizing Costs
  ☑ Reorder Points
  ☑ Production Order Quantity Model
  ☑ Quantity Discount Models
Outline – Continued

☑ Probabilistic Models and Safety Stock
☑ Other Probabilistic Models
☑ Fixed-Period (P) Systems

Learning Objectives

When you complete this chapter, you should be able to:

Identify or Define:

☑ ABC analysis
☑ Record accuracy
☑ Cycle counting
☑ Independent and dependent demand
☑ Holding, ordering, and setup costs
Learning Objectives

When you complete this chapter, you should be able to:

Describe or Explain:

- The functions of inventory and basic inventory models

Amazon.com

- Amazon.com started as a “virtual” retailer – no inventory, no warehouses, no overhead; just computers taking orders to be filled by others
- Growth has forced Amazon.com to become a world leader in warehousing and inventory management
1. Each order is assigned by computer to the closest distribution center that has the product(s)

2. A “flow meister” at each distribution center assigns work crews

3. Lights indicate products that are to be picked and the light is reset

4. Items are placed in crates on a conveyor. Bar code scanners scan each item 15 times to virtually eliminate errors.

5. Crates arrive at central point where items are boxed and labeled with new bar code

6. Gift wrapping is done by hand at 30 packages per hour

7. Completed boxes are packed, taped, weighed and labeled before leaving warehouse in a truck

8. Order arrives at customer within a week
Inventory

- One of the most expensive assets of many companies representing as much as 50% of total invested capital
- Operations managers must balance inventory investment and customer service

Functions of Inventory

1. To decouple or separate various parts of the production process
2. To decouple the firm from fluctuations in demand and provide a stock of goods that will provide a selection for customers
3. To take advantage of quantity discounts
4. To hedge against inflation
Types of Inventory

- **Raw material**
  - Purchased but not processed
- **Work-in-process**
  - Undergone some change but not completed
  - A function of cycle time for a product
- **Maintenance/repair/operating (MRO)**
  - Necessary to keep machinery and processes productive
- **Finished goods**
  - Completed product awaiting shipment

The Material Flow Cycle

![Diagram of material flow cycle](image)

Figure 12.1
Inventory Management

☑ How inventory items can be classified
☑ How accurate inventory records can be maintained

ABC Analysis

☑ Divides inventory into three classes based on annual dollar volume
   ✔ Class A - high annual dollar volume
   ✔ Class B - medium annual dollar volume
   ✔ Class C - low annual dollar volume

☑ Used to establish policies that focus on the few critical parts and not the many trivial ones
## ABC Analysis

ABC Analysis

- Other criteria than annual dollar volume may be used
  - Anticipated engineering changes
  - Delivery problems
  - Quality problems
  - High unit cost
ABC Analysis

☑ Policies employed may include
  ☑ More emphasis on supplier development for A items
  ☑ Tighter physical inventory control for A items
  ☑ More care in forecasting A items

Record Accuracy

☑ Accurate records are a critical ingredient in production and inventory systems
☑ Allows organization to focus on what is needed
☑ Necessary to make precise decisions about ordering, scheduling, and shipping
☑ Incoming and outgoing record keeping must be accurate
☑ Stockrooms should be secure
Cycle Counting

- Items are counted and records updated on a periodic basis
- Often used with ABC analysis to determine cycle
- Has several advantages
  - Eliminates shutdowns and interruptions
  - Eliminates annual inventory adjustment
  - Trained personnel audit inventory accuracy
  - Allows causes of errors to be identified and corrected
  - Maintains accurate inventory records

Cycle Counting Example

5,000 items in inventory, 500 A items, 1,750 B items, 2,750 C items

Policy is to count A items every month (20 working days), B items every quarter (60 days), and C items every six months (120 days)

<table>
<thead>
<tr>
<th>Item Class</th>
<th>Quantity</th>
<th>Cycle Counting Policy</th>
<th>Number of Items Counted per Day</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>500</td>
<td>Each month</td>
<td>500/20 = 25/day</td>
</tr>
<tr>
<td>B</td>
<td>1,750</td>
<td>Each quarter</td>
<td>1,750/60 = 29/day</td>
</tr>
<tr>
<td>C</td>
<td>2,750</td>
<td>Every 6 months</td>
<td>2,750/120 = 23/day</td>
</tr>
</tbody>
</table>

Total: 77/day
Control of Service Inventories

- Can be a critical component of profitability
- Losses may come from shrinkage or pilferage
- Applicable techniques include
  1. Good personnel selection, training, and discipline
  2. Tight control on incoming shipments
  3. Effective control on all goods leaving facility

Independent Versus Dependent Demand

- Independent demand - the demand for item is independent of the demand for any other item in inventory
- Dependent demand - the demand for item is dependent upon the demand for some other item in the inventory
Holding, Ordering, and Setup Costs

- **Holding costs** - the costs of holding or “carrying” inventory over time
- **Ordering costs** - the costs of placing an order and receiving goods
- **Setup costs** - cost to prepare a machine or process for manufacturing an order

### Holding Costs

<table>
<thead>
<tr>
<th>Category</th>

</tbody>
</table>

Table 12.1
Inventory Models for Independent Demand

Need to determine when and how much to order

- Basic economic order quantity
- Production order quantity
- Quantity discount model

Basic EOQ Model

Important assumptions

1. Demand is known, constant, and independent
2. Lead time is known and constant
3. Receipt of inventory is instantaneous and complete
4. Quantity discounts are not possible
5. Only variable costs are setup and holding
6. Stockouts can be completely avoided
Inventory Usage Over Time

Order quantity = Q (maximum inventory level)

Usage rate

Average inventory on hand \( \frac{Q}{2} \)

Minimum inventory

Time

Minimizing Costs

Objective is to minimize total costs

Annual cost

Curve for total cost of holding and setup

Minimum total cost

Holding cost curve

Setup (or order) cost curve

Table 11.5

Optimal order quantity

Order quantity
The EOQ Model

\[ Q = \text{Number of pieces per order} \]
\[ Q^* = \text{Optimal number of pieces per order (EOQ)} \]
\[ D = \text{Annual demand in units for the Inventory item} \]
\[ S = \text{Setup or ordering cost for each order} \]
\[ H = \text{Holding or carrying cost per unit per year} \]

Annual setup cost = \( \frac{D}{Q} S \)

Annual holding cost = \( \frac{D}{Q} \frac{Q}{2} H \)

Annual setup cost = (Number of orders placed per year) x (Setup or order cost per order)

\[
= \left( \frac{\text{Annual demand}}{\text{Number of units in each order}} \right) \left( \frac{\text{Setup or order cost per order}}{\text{Average inventory level}} \right)
\]

\[
= \left( \frac{D}{Q} \right) S
\]
The EOQ Model

Q = Number of pieces per order
Q* = Optimal number of pieces per order (EOQ)
D = Annual demand in units for the Inventory item
S = Setup or ordering cost for each order
H = Holding or carrying cost per unit per year

Optimal order quantity is found when annual setup cost equals annual holding cost

\[ \frac{D}{Q} S = \frac{Q}{2} H \]

Solving for Q*

\[ 2DS = Q^2H \]
\[ Q^2 = \frac{2DS}{H} \]
\[ Q^* = \sqrt{\frac{2DS}{H}} \]

An EOQ Example

Determine optimal number of needles to order
D = 1,000 units
S = $10 per order
H = $.50 per unit per year

\[ Q^* = \sqrt{\frac{2DS}{H}} \]
\[ Q^* = \sqrt{\frac{2(1,000)(10)}{0.50}} = \sqrt{40,000} = 200 \text{ units} \]
An EOQ Example

Determine optimal number of needles to order

\[ D = 1,000 \text{ units} \quad Q^* = 200 \text{ units} \]

\[ S = $10 \text{ per order} \]

\[ H = \$.50 \text{ per unit per year} \]

\[ N = \frac{\text{Demand}}{\text{Order quantity}} = \frac{D}{Q^*} \]

\[ N = \frac{1,000}{200} = 5 \text{ orders per year} \]

An EOQ Example

Determine optimal number of needles to order

\[ D = 1,000 \text{ units} \quad Q^* = 200 \text{ units} \]

\[ S = $10 \text{ per order} \quad N = 5 \text{ orders per year} \]

\[ H = \$.50 \text{ per unit per year} \]

\[ T = \frac{\text{Number of working days per year}}{N} \]

\[ T = \frac{250}{5} = 50 \text{ days between orders} \]
An EOQ Example

Determine optimal number of needles to order

\[
D = 1,000 \text{ units} \quad Q^* = 200 \text{ units}
\]

\[
S = $10 \text{ per order} \quad N = 5 \text{ orders per year}
\]

\[
H = $.50 \text{ per unit per year} \quad T = 50 \text{ days}
\]

Total annual cost = Setup cost + Holding cost

\[
TC = \frac{D}{Q}S + \frac{Q}{2}H
\]

\[
TC = \frac{1,000}{200}($10) + \frac{200}{2}($.50)
\]

\[
TC = (5)($10) + (100)($.50) = $50 + $50 = $100
\]

Robust Model

- The EOQ model is robust
- It works even if all parameters and assumptions are not met
- The total cost curve is relatively flat in the area of the EOQ
An EOQ Example

Management underestimated demand by 50%

\[ D = 1,000 \text{ units} \]
\[ Q^* = 200 \text{ units} \]
\[ S = \$10 \text{ per order} \]
\[ N = 5 \text{ orders per year} \]
\[ H = \$.50 \text{ per unit per year} \]
\[ T = 50 \text{ days} \]

\[ TC = \frac{D}{Q}S + \frac{Q}{2}H \]

\[ TC = \frac{1,500}{200}($10) + \frac{200}{2}(.50) = \$75 + \$50 = \$125 \]

Total annual cost increases by only 25%

An EOQ Example

Actual EOQ for new demand is 244.9 units

\[ D = 1,000 \text{ units} \]
\[ Q^* = 244.9 \text{ units} \]
\[ S = \$10 \text{ per order} \]
\[ N = 5 \text{ orders per year} \]
\[ H = \$.50 \text{ per unit per year} \]
\[ T = 50 \text{ days} \]

\[ TC = \frac{D}{Q}S + \frac{Q}{2}H \]

\[ TC = \frac{1,500}{244.9}($10) + \frac{244.9}{2}(.50) \]

\[ TC = \$61.24 + \$61.24 = \$122.48 \]

Only 2% less than the total cost of $125 when the order quantity was 200
Reorder Points

- EOQ answers the “how much” question.
- The reorder point (ROP) tells when to order.

\[
ROP = \left( \frac{\text{Demand per day}}{} \right) \left( \text{Lead time for a new order in days} \right) = d \times L
\]

\[
d = \frac{D}{\text{Number of working days in a year}}
\]

Reorder Point Curve

Figure 12.5
Reorder Point Example

Demand = 8,000 DVDs per year
250 working day year
Lead time for orders is 3 working days

\[
d = \frac{D}{\text{Number of working days in a year}}
\]

\[
= \frac{8,000}{250} = 32 \text{ units}
\]

ROP = \(d \times L\)

\[
= 32 \text{ units per day} \times 3 \text{ days} = 96 \text{ units}
\]

Production Order Quantity Model

☑ Used when inventory builds up over a period of time after an order is placed

☑ Used when units are produced and sold simultaneously
Production Order Quantity Model

Q = Number of pieces per order  
\( p = \) Daily production rate  
\( H = \) Holding cost per unit per year  
\( d = \) Daily demand/usage rate  
\( t = \) Length of the production run in days

\[
\left\{\begin{array}{l}
\text{Annual inventory holding cost} = (\text{Average inventory level}) \times (\text{Holding cost per unit per year}) \\
\text{Average inventory level} = (\text{Maximum inventory level})/2 \\
\text{Maximum inventory level} = \left(\frac{\text{Total produced during the production run}}{\text{Total used during the production run}}\right) - pt - dt
\end{array}\right.
\]
Production Order Quantity Model

- **Q** = Number of pieces per order
- **p** = Daily production rate
- **H** = Holding cost per unit per year
- **d** = Daily demand/usage rate
- **t** = Length of the production run in days

\[
\text{Maximum inventory level} = \left( \text{Total produced during the production run} \right) - \left( \text{Total used during the production run} \right) = pt - dt
\]

However, \( Q = \text{total produced} = pt \) ; thus \( t = Q/p \)

\[
\text{Maximum inventory level} = p \left( \frac{Q}{p} \right) - d \left( \frac{Q}{p} \right) = Q \left( 1 - \frac{d}{p} \right)
\]

Holding cost = \[
\frac{\text{Maximum inventory level}}{2} (H) = \frac{Q}{2} \left[ 1 - \left( \frac{d}{p} \right) \right] H
\]

Production Order Quantity Model

- **Q** = Number of pieces per order
- **p** = Daily production rate
- **H** = Holding cost per unit per year
- **d** = Daily demand/usage rate
- **D** = Annual demand

\[
\text{Setup cost} = \left( \frac{D}{Q} \right) S
\]

Holding cost = \[
\frac{1}{2} HQ \left[ 1 - \left( \frac{d}{p} \right) \right]
\]

\[
\left( \frac{D}{Q} \right) S = \frac{1}{2}HQ \left[ 1 - \left( \frac{d}{p} \right) \right]
\]

\[
Q^2 = \frac{2DS}{H[1 - (d/p)]}
\]

\[
Q^* = \sqrt{\frac{2DS}{H[1 - (d/p)]}}
\]
Production Order Quantity Example

\[ Q^* = \sqrt{\frac{2DS}{H[1 - (d/p)]}} \]

\[ Q^* = \sqrt{\frac{2(1,000)(10)}{0.50[1 - (4/8)]}} = \sqrt{80,000} \]

\[ = 282.8 \text{ or } 283 \text{ hubcaps} \]

Production Order Quantity Model

When annual data are used the equation becomes

\[ Q^* = \sqrt{\frac{2DS}{H\left[1 - \frac{\text{annual demand rate}}{\text{annual production rate}}\right]}} \]
Quantity Discount Models

- Reduced prices are often available when larger quantities are purchased
- Trade-off is between reduced product cost and increased holding cost

Total cost = Setup cost + Holding cost + Product cost

\[ TC = \frac{D}{Q} S + \frac{QH}{2} + PD \]

A typical quantity discount schedule

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 12.2
Quantity Discount Models

Steps in analyzing a quantity discount

1. For each discount, calculate Q*
2. If Q* for a discount doesn’t qualify, choose the smallest possible order size to get the discount
3. Compute the total cost for each Q* or adjusted value from Step 2
4. Select the Q* that gives the lowest total cost

Quantity Discount Models

Figure 12.7
Quantity Discount Example

Calculate $Q^*$ for every discount

$Q^* = \sqrt{\frac{2DS}{IP}}$

$Q_1^* = \sqrt{\frac{2(5,000)(49)}{(.2)(5.00)}} = 700 \text{ cars order}$

$Q_2^* = \sqrt{\frac{2(5,000)(49)}{(.2)(4.80)}} = 714 \text{ cars order}$

$Q_3^* = \sqrt{\frac{2(5,000)(49)}{(.2)(4.75)}} = 718 \text{ cars order}$
### Quantity Discount Example

</tbody>
</table>

Table 12.3

Choose the price and quantity that gives the lowest total cost

*Buy 1,000 units at $4.80 per unit*

---

### Probabilistic Models and Safety Stock

- Used when demand is not constant or certain
- Use safety stock to achieve a desired service level and avoid stockouts

\[
ROP = d \times L + ss
\]

Annual stockout costs = the sum of the units short
\* the probability \* the stockout cost/unit
\* the number of orders per year
## Safety Stock Example

ROP = 50 units  
Stockout cost = $40 per frame  
Orders per year = 6  
Carrying cost = $5 per frame per year

<table>
<thead>
<tr>
<th>Number of Units</th>
<th>Probability</th>
</tr>
</thead>
<tbody>

Probabilistic Demand

Probability of no stockout 95% of the time

Risk of a stockout (5% of area of normal curve)

Mean demand 350

ROP = ? kits

Safety stock 16.5 units

0

z

Number of standard deviations

Quantity
**Probabilistic Demand**

*Use prescribed service levels to set safety stock when the cost of stockouts cannot be determined*

\[
\text{ROP} = \text{demand during lead time} + Z\sigma_{\text{dlt}}
\]

where

- \( Z \) = number of standard deviations
- \( \sigma_{\text{dlt}} \) = standard deviation of demand during lead time

**Probabilistic Example**

Average demand = \( \mu = 350 \) kits

Standard deviation of demand during lead time = \( \sigma_{\text{dlt}} = 10 \) kits

5% stockout policy (service level = 95%)

*Using Appendix I, for an area under the curve of 95%, the \( Z = 1.65 \)*

Safety stock = \( Z\sigma_{\text{dlt}} = 1.65(10) = 16.5 \) kits

Reorder point = expected demand during lead time + safety stock

= 350 kits + 16.5 kits of safety stock

= 366.5 or 367 kits
Other Probabilistic Models

When data on demand during lead time is not available, there are other models available

1. When demand is variable and lead time is constant
2. When lead time is variable and demand is constant
3. When both demand and lead time are variable

When data on demand during lead time is not available, there are other models available

Other Probabilistic Models

Demand is variable and lead time is constant

$$\text{ROP} = (\text{average daily demand} \times \text{lead time in days}) + Z\sigma_{dlt}$$

where

$$\sigma_d = \text{standard deviation of demand per day}$$

$$\sigma_{dlt} = \sigma_d \sqrt{\text{lead time}}$$
Probabilistic Example

Average daily demand (normally distributed) = 15
Standard deviation = 5
Lead time is constant at 2 days  \( Z \) for 90% = 1.28
90% service level desired  From Appendix I

\[
ROP = (15 \text{ units} \times 2 \text{ days}) + Z\sigma_{\text{dlt}} \\
= 30 + 1.28(5)(\sqrt{2}) \\
= 30 + 8.96 = 38.96 \approx 39
\]

Safety stock is about 9 units

Other Probabilistic Models

Lead time is variable and demand is constant

\[
ROP = (\text{daily demand} \times \text{average lead time in days}) + Z \times (\text{daily demand}) \times \sigma_{\text{lt}}
\]

where  \( \sigma_{\text{lt}} = \text{standard deviation of lead time in days} \)
Probabilistic Example

Daily demand (constant) = 10  
Average lead time = 6 days  
Standard deviation of lead time = $\sigma_{lt} = 3$  
98% service level desired

Z for 98% = 2.055  
From Appendix I

\[ ROP = (10 \text{ units } \times 6 \text{ days}) + 2.055(10 \text{ units})(3) \]
\[ = 60 + 61.55 = 121.55 \]

Reorder point is about 122 units

Other Probabilistic Models

Both demand and lead time are variable

\[ ROP = (\text{average daily demand} \times \text{average lead time}) + Z\sigma_{dlit} \]

where  
$\sigma_d = \text{standard deviation of demand per day}$  
$\sigma_{lt} = \text{standard deviation of lead time in days}$  
$\sigma_{dlit} = \sqrt{(\text{average lead time} \times \sigma_d^2) + (\text{average daily demand})^2\sigma_{lt}^2}$
Probabilistic Example

Average daily demand (normally distributed) = 150
Standard deviation = $\sigma_d = 16$
Average lead time 5 days (normally distributed)
Standard deviation = $\sigma_{lt} = 1$ day

95% service level desired

\[ Z \text{ for } 95\% = 1.65 \]
\[ \text{From Appendix I} \]

\[ ROP = (150 \text{ packs x 5 days}) + 1.65\sigma_{dlt} \]
\[ = (150 \times 5) + 1.65 \sqrt{(5 \text{ days x } 16^2)} + (150^2 \times 1^2) \]
\[ = 750 + 1.65(154) = 1,004 \text{ packs} \]

Fixed-Period (P) Systems

✔ Orders placed at the end of a fixed period
✔ Inventory counted only at end of period
✔ Order brings inventory up to target level

✔ Only relevant costs are ordering and holding
✔ Lead times are known and constant
✔ Items are independent from one another
**Fixed-Period (P) Systems**

![Diagram of Fixed-Period (P) Systems]

**Fixed-Period (P) Example**

3 jackets are back ordered
It is time to place an order
No jackets are in stock
Target value = 50

Order amount \( (Q) = \text{Target (}T\text{)} - \text{On-hand inventory} - \text{Earlier orders not yet received} + \text{Back orders} \)

\[ Q = 50 - 0 - 0 + 3 = 53 \text{ jackets} \]
**Fixed-Period Systems**

- Inventory is only counted at each review period
- May be scheduled at convenient times
- Appropriate in routine situations
- May result in stockouts between periods
- May require increased safety stock
