

# Research Essentials: Making Sense of What you Read

**Einas Al-Eisa, MSc, PhD**

# Objectives

- Learn the basics??
- Learn to synthesize published information??
- Start your own project??
- Argue with physicians in rounds??
- **Be a better clinician** ✓

# Interactive Sessions

For active learners

# Outline

- Definition of research
- Why research?
- Evidence-based medicine
- Who should research
- Barriers of research
- Developing answerable research problem

# Definition of Research

- “The process by which we determine whether what we do as physical therapists makes a difference in the lives of the people we serve”  
(Domholdt, 2000)

# Why research?

# Why research?

1. To establish a **body of knowledge** for physical therapy
  - For the survival of a profession
  - Stop borrowing from other disciplines!!

# Why research?

2. To determine the **efficacy** of physical therapy treatments
  - Research should not be undertaken to show that what we do works (***Bias** error*)
    - We should study **whether** what we do works

# Why research?

## 3. Improve **patient care**

- Helping clinicians make decisions about the use of **existing practices**
- Test **new procedures**

Physical therapists must be willing to:

```
graph TD; A[Physical therapists must be willing to:] --- B[Search for evidence (effectiveness of practice?)]; A --- C[Modify the practice in response to the evidence]
```

Search for **evidence**  
(effectiveness of practice?)

**Modify** the practice  
in response to the evidence

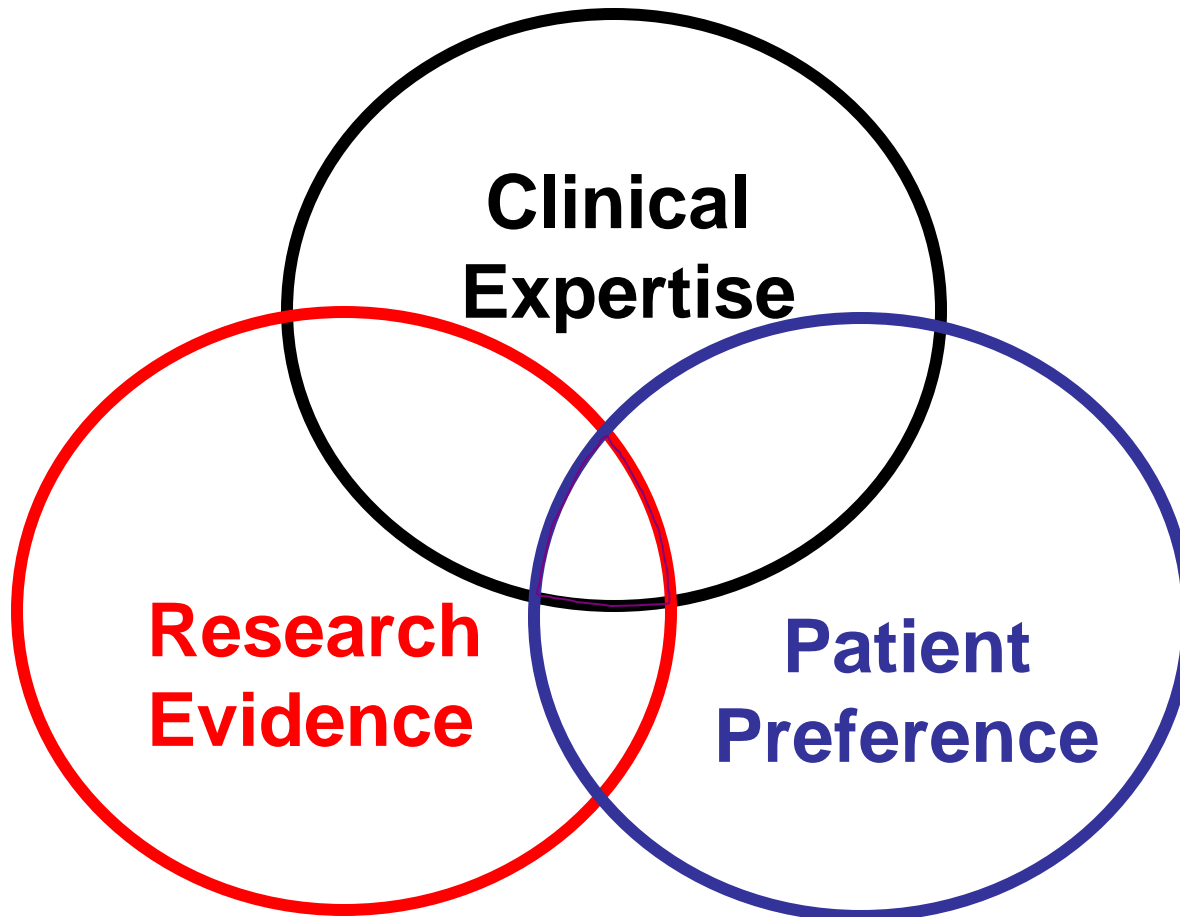

Knowledge of research design &  
data analysis

evaluate existing evidence &  
produce new evidence

EBM???

# Evidence-based Medicine

# Evidence-based Medicine

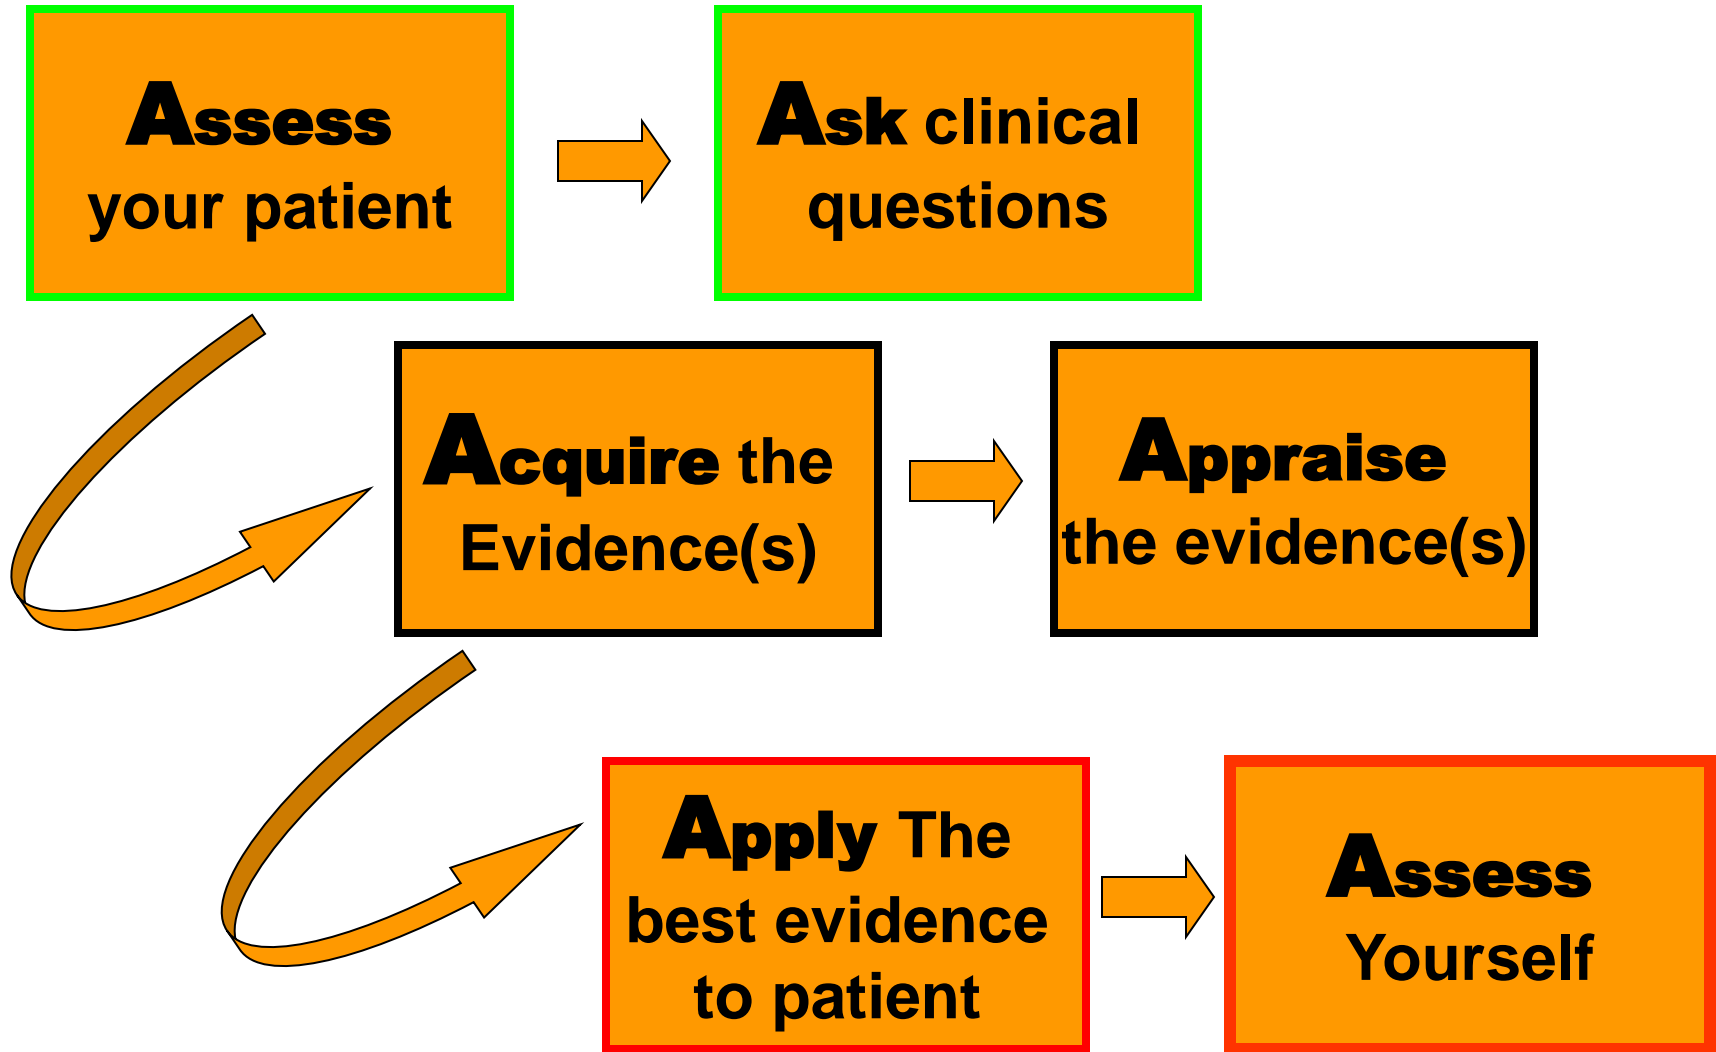

Integrating the:

- ✓ best research evidence with
- ✓ clinical expertise
- ✓ patient values

(Brinkley et al., 1999)

Haven't all concerned physicians  
been doing this EBM for ages... ?

# 5 Steps to Evidence-based practice

1. Define the **question**
2. **Collect the best evidence** related to the question
3. **Critically appraise** the evidence

# 5 Steps to Evidence-based practice

4. **Integrate** the evidence with clinical expertise & patient factors to make a decision
5. **Evaluate** the process so it can be improved next time

Knowledge of research design and  
data analysis is a prerequisite

evaluate existing evidence and  
produce new evidence

# EBM Step 1

- Formulate a clinically relevant and “searchable” question

# Developing answerable research **problem**

“The challenge in searching for a research question is not a shortage of uncertainties in the universe; it is the difficulty in finding an **important** one that can be transformed into a **feasible** and valid **study plan**”

(Cummings et al., 1988)

# Example

- **Topic:** Low Back Pain (LBP)
- **Problem:** the popular use of back support to prevent LBP

# Questions:

- Do back support increase intra-abdominal pressure?
- How well do different back supports unload the spine?
- Do back support preserve the endurance of the back extensor muscles?

# A good research problem is:

- **Feasible** (subjects, equipment, time, technical support, money)
- **Interesting** (to the investigator)
- **Novel** (challenge the old)
- **Can be studied ethically** (with no negative impact on the subjects)
- **Relevant** (who cares?)

# EBM Step 2

## Find the Evidence

But Too many articles retrieved...

How do you find the best evidence?

# EBM Step 3

## Critical Appraisal

- Are the results of the study likely to be true?
- Are the results likely to be free of systematic bias?

***Rx***

***Intervention  
RCT***

***Dx***

***Diagnostic***

***Review***

***Systematic  
Meta-analysis***

# EBM Step 4

## Integrate evidence & practice

If the **methods** are **valid**:

–What are the **results**?

–Magnitude of results?

➤ Study design

➤ Conflicting results

# Conflicting Results--

What's the truth?

**EBM will NOT tell you  
what to do!**

# What will determine what you do:

The integration of

- individual clinical expertise

with the:

- best available external clinical evidence from systematic research

# Who should research?

Members of the profession that:

- Have interest in a particular area
- Are motivated & willing to devote effort & time
- Possess considerable knowledge of the area being investigated
- Are familiar with the procedures of conducting research & analyzing the results
  - Clinical researcher = practitioner & investigator

# Barriers of research

- Unfamiliarity with research
- Unfamiliarity with statistics
- Lack of funding
- Lack of equipment & facilities
- Lack of time
- Lack of administrative support

# RHS 481 Suggested Topics

- Adherence / Compliance
- Physical activity
- Health & Wellness Promotion
- Low back pain

# RHS 481 Suggested Topics

- EMG of transverse abdominus and multifidus during Pilates exercises on and off Swiss ball

# THINK BIG !

start small

**ACT NOW**

# Fundamental concepts

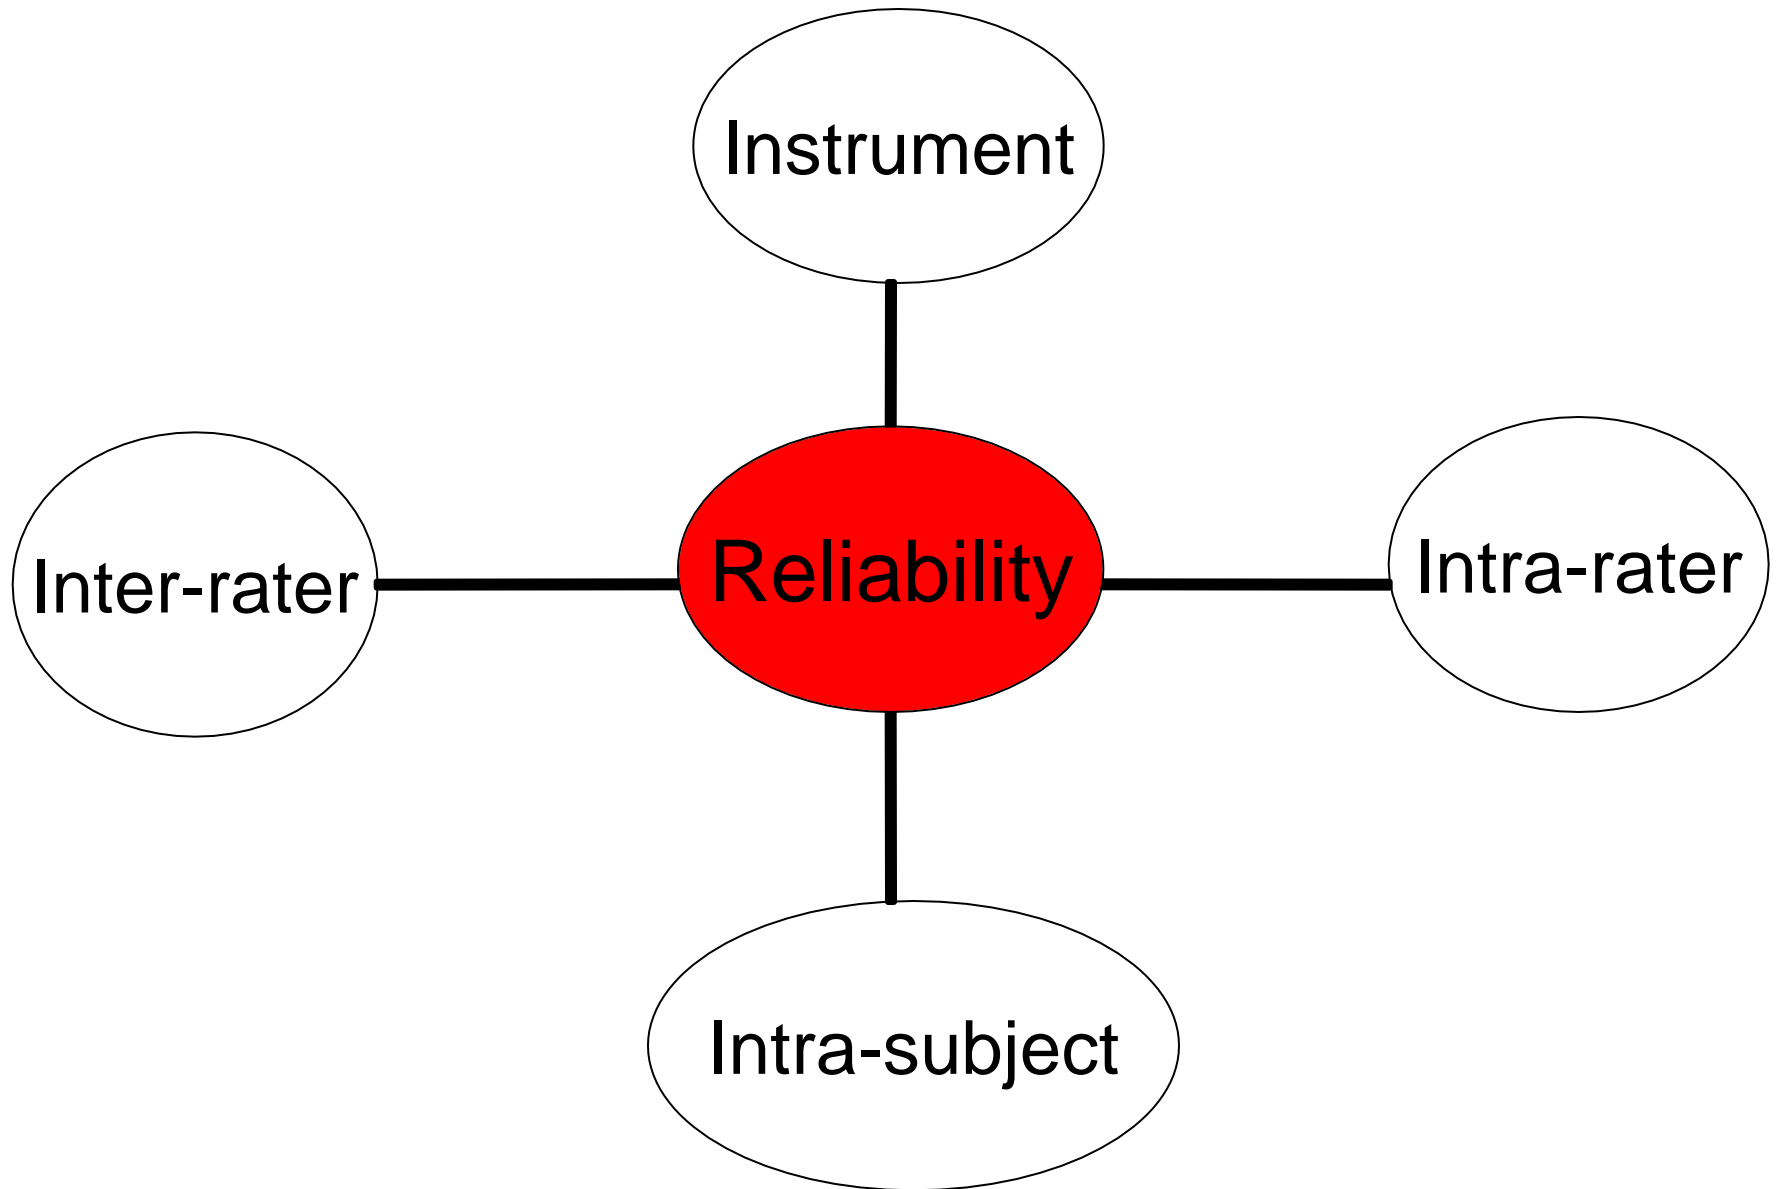

# Reliability

- **Reliability** (consistency) = the degree to which test scores are free from error
  - ***Instrument reliability*** = measurement error
  - ***Intra-rater reliability*** = consistency with which one rater assigns scores to the same thing on two occasions

# Reliability

- ***Inter-rater reliability*** = consistency among different raters in assigning scores to the same thing
- ***Intra-subject reliability*** = related to change in subject performance from time to time

# Research validity

- The extent to which the conclusions of the research are believable and useful

**External Validity**

**Population**

**Conclusion**

# Types of validity

## **Internal validity:**

- The extent to which the results demonstrate that a causal relationship exists between the independent and dependent variables
- Is the research designed so that there are only few alternative explanations for changes in the dependent variable other than the effect of the independent variable?

# Types of validity

## Internal validity:

- To increase internal validity —————> maximize the control over all aspects of the study
- Example: eliminating ***confounding*** (extraneous) variables through *control* of the experimental setting to eliminate their effects on the dependent variable
- Should be planned as early as the proposal

# Types of validity

## **Construct validity:**

- Concerned with the meaning of variables within the study
- Are the research constructs defined so that the research can be placed in the framework of other research within the field?

# Types of validity

## Construct (criterion) validity:

- *Labeled* versus *implemented* construct
- Example: using active range of motion as a dependent measure of shoulder function. Labeled construct is “function”, and implemented construct is “range of motion”

# Types of validity

## External validity:

- To whom, in what settings, and at what times can the results be ***generalized?***
- To whom can the results of this research be ***applied?***

# Types of validity

## **External validity:**

- Requires thoughtful consideration of the population to whom the results of the study can be applied

# Types of validity

## **Statistical conclusion validity:**

- Are statistical tests used correctly to analyze the data?

# Validity

## Example

- To achieve a high level of *internal validity*, researchers standardize the experimental treatment to control confounding variables.
- Such standardization compromises *external validity* because the results can be applied only to settings in which the treatment can be controlled.

# THINK BIG !

start small

# Methods of obtaining knowledge

## Research Paradigms

```
graph TD; A[Research Paradigms] --- B[Quantitative Paradigm: Study of groups whose treatment is manipulated]; A --- C[Qualitative Paradigm: Broad description of a phenomenon without manipulation]; A --- D[Single-system Paradigm: Individual responses to manipulation];
```

**Quantitative Paradigm:**  
Study of groups whose treatment is manipulated

**Qualitative Paradigm:**  
Broad description of a phenomenon without manipulation

**Single-system Paradigm:**  
Individual responses to manipulation
