

## Chapter 3

### Measurements of disease frequency

#### Objectives:

By the end of this lecture, students should be able to:

1. Enumerate correctly measurements of disease frequency.
2. Differentiate between morbidity and mortality rates.
3. Recognize difference between rates and ratios.
4. Discuss factors affecting different rates.
5. Identify uses of morbidity and mortality rates

#### A. Morbidity rates

Morbidity rate: A disease rate, specifically prevalence and incidence rates of diseases in a population in a specified time period.

#### *Morbidity Measures*

##### 1. Incidence rate

Incidence: The rate or the development of **new cases** of a condition or disease in a population in a **specified time period**; in previously disease-free or condition-free ("**at risk** ") individuals. It provides an estimate of the condition/disease risk in that population.

No. Of persons developing a disease

(New cases) in a specific time & locality

Incidence Rate = ----- x 1000

Total population at risk during that period of time

Incidence is always calculated for a given period of time

**An attack rate** is an incidence rate calculated for a specific disease for a limited period of time during an epidemic

### Attack Rate

An attack rate is a variant of an incidence rate, applied to a narrowly defined population observed for a limited time, such as during an epidemic.

The attack rate is usually expressed as % percent.

☒ **Special incidence rate**

☒ **Limited period of risk (epidemic)**

☒ **Risk restricted to a special age group**

Example

250 persons who attended a picnic, 90 subsequently developed gastroenteritis.

Calculate the attack rate of gastroenteritis

Attendees = 250

ILL = 90

Attack rate =  $(90 \div 250) \times 100 = 36 \%$

### Recovery Rate

$$\frac{\text{No. Of recoveries from a certain disease in a certain Period of time in a certain area}}{\text{No. Of ill person in the same period of time and same area}} \times 100$$

## 2.Prevalence

Prevalence measures the number of cases (new and old) of the disease (or other health-related phenomenon) at a point or period in time.

### Morbidity Measures

$$\text{Prevalence} = \frac{\text{Number of existing events, old and new}}{\text{Population at risk}} \times 1,000$$

- Prevalence is not a rate
- **Point prevalence** measures the frequency of all current events (old and new) at a given instant in time
- **Period prevalence** measures the frequency of all current events (old and new) for a prescribed period of time

*Epidemiology (Schneider)*

### Prevalence

The presence (proportion) of disease or condition in a population (generally irrespective of the duration of the disease)

Prevalence: Quantifies the "burden" of disease.

- Point Prevalence
- Period Prevalence

## ***“Point” Prevalence***

$$P = \frac{\text{Number of existing cases}}{\text{Total population}}$$

At a set point in time  
(i.e. September 30, 1999)

## ***“Point” Prevalence***

### Example:

On June 30, 1999, neighborhood A has:

- population of 1,600
- 29 current cases of hepatitis B

So,  $P = 29 / 1600 = 0.018$  or 1.8%

## NOTES

- 1-Prevalence rates indicate amount of illness requiring care.
- 2- Easier to measure than incidence rate.
- 3- Low incidence diseases become important public health problems due to high prevalence
- 4- Prevalence rate is unsuitable for short duration diseases (rapid recovery or fatal)

**Example 2:**

The total population estimate for Jeddah city on March 1, 1987 was 140,600.

\*new cases of tuberculosis= 133

\*total cases of tuberculosis as of march 1=400

\* Total of recovery cases= 100

**Calculate the following**

**1.Point prevalence (pp):**

(No. Of current (old+ new) of a specified disease existing at a given  
Point of time in a locality)

$$PP = \frac{\text{-----}}{\text{(The total number of population at the same point of time in the same locality)}} \times 1000$$

$$= \frac{400}{140,600} \times 1000$$

$$= 2.845$$

**2.Incidence rate (IR):**

No. of persons developing a disease  
(New cases) in a specific time &locality

$$IR = \frac{\text{-----}}{\text{Total population at risk during that period of time}} \times 1000$$

$$= 133 \setminus 140,600 \times 1000 = , 9459$$

### 3. Recovery cases (RC):

No. of recoveries from a certain disease in a certain

Period of time in a certain area

X100

$$RC = \frac{\text{No. of recoveries from a certain disease in a certain period of time in a certain area}}{\text{No. of ill person in the same period of time and same area}} \times 100$$

No. of ill person in the same period of time and same area

100

$$= \frac{400}{16000} \times 100$$

400

= 25

***“Period” Prevalence***

**Number of existing cases**

**Pp =**  $\frac{\text{-----}}{\text{Total population}}$

**During a time period**  
**(i.e. May 1 - July 31, 1999)**

**Includes existing cases on May 1, and those newly diagnosed until July 31.**

(Total Number of cases (pre-existing and new) of disease during given time period)

$$\text{Period prevalence rate} = 1000X \frac{\text{Total population at the same time period}}{\text{Total Number of cases (pre-existing and new) of disease during given time period}}$$

### ***“Period” Prevalence***

#### ***Example:***

Between June 30 and August 30, 1999, neighborhood A has:

- average population of 1,600
- 29 existing cases of hepatitis B on June 30
- 6 incident (new) cases of hepatitis B between July 1 and August 30

So,  $P_p = (29 + 6) / 1600 = 0.022$  or 2.2%

#### **Relation between incidence and prevalence:**

- Prevalence ~ incidence x duration of disease
- Higher incidence results in higher prevalence
- Longer duration results in higher prevalence

Variation in relation between Incidence and prevalence

Disease in which incidence is stable and prevalence is increasing

### Factors affecting Prevalence:

- **Changes in incidence**

High incidence produces high prevalence

- **Changes in disease duration and chronicity**

Longer duration of disease, higher prevalence

- **Intervention programs**

Better treatment with high cure rate decrease prevalence

- **Changes in social customs**

### Factors affecting incidence rate:

- **New risk factor**

New virus (HIV and AIDS)

- **Changing habits**

- fluoridated water and decrease in dental caries

- **Changing virulence of causative organisms**

- drug-resistant bacteria (TB)

- **Changing of intervention programs**

- Polio eradication campaigns polio

- **Population pattern**

- Aging Degenerative diseases

- **Reporting**

- Increase reporting incidence

- **Screening**

- Early detection of cases incidence

- **New diagnostic tools**

- New diagnostic tools detection of cases

Factors affecting Prevalence:

- Changes in incidence
- High incidence produces high prevalence
- Changes in disease duration and chronicity
- Longer duration of disease, higher prevalence
- Intervention programs
- Better treatment with high cure rate decrease prevalence
- Changes in social customs
- Factors affecting incidence rate:
  - New risk factor
  - New virus (HIV and AIDS)
  - Changing habits
  - fluoridated water and decrease in dental caries
  - Changing virulence of causative organisms
  - drug-resistant bacteria (TB)

- Changing of intervention programs
- Polio eradication campaigns polio
- Population pattern
- Aging Degenerative diseases
  
- Reporting
- Increase reporting incidence
- Screening
- Early detection of cases incidence
- New diagnostic tools
- New diagnostic tools detection of cases
