Solar Energy

UNIT TWO

THERMAL RADIATION

Unit Outline

2

- Electromagnetic radiation
- Thermal radiation
- Blackbody radiation
- Radiation emitted from a real surface
- Irradiance
- Kirchhoff's Law
- Diffuse and gray surface
- View factor
- Radiation exchange between black bodies
- Radiation from a diffuse, gray surface

- The electromagnetic energy emitted by matter as a result of the changes in the electronic configurations of the atoms or molecules.
- Electromagnetic radiation energy is transported by waves
- These waves have a frequency (ν) and wavelength (λ).

- Frequency ν and wavelength λ Are related by:

$$\lambda = \frac{c}{\nu}$$

where,

$$C = C_0 / n$$

C : the speed of propagation of a wave in the medium

$C_0 = 2.9979 \times 10^8$ m/s, the *speed of light* in a vacuum

n , the *index of refraction* of that medium

Examples:

$n = 1$ (air and most gases)

$n = 1.5$ (glass)

$n = 1.33$ (water)

- Radiation differs from conduction and convection
- It does not require the presence of a material medium
- Radiation transfer occurs in all types of matter (solid, liquid, or gas)

- Electromagnetic radiation can be viewed as the propagation of a collection of discrete packets of energy called **photons** or **quanta**.
- In this view, each photon of frequency (ν) is considered to have an energy of:

$$e = h\nu = \frac{hc}{\lambda}$$

where h is called Planck's constant

$$h = 6.6256 \times 10^{-34} \text{ J.s}$$

- This means that the energy of a photon is inversely proportional to its wavelength

Thermal Radiation

8

- Thermal radiation is the part of electromagnetic radiation that primarily creates a heating effect.
- Thermal radiation is emitted as a result of energy transitions of molecules, atoms, and electrons of a substance.
- Temperature is a measure of the strength of these activities at the microscopic level
- Therefore, thermal radiation emission increases with increasing temperature

Thermal Radiation

9

- Thermal radiation mainly covers:
 - Infrared radiation
 - Visible light
 - Ultraviolet radiation
- Thermal radiation is continuously emitted by all matter whose temperature is above absolute zero.

- Electromagnetic radiation
- Thermal radiation
- Blackbody radiation
- Radiation emitted from a real surface
- Irradiance
- Kirchhoff's Law

Blackbody Radiation

11

- A blackbody is a body that absorbs ***all*** the incident radiation regardless of wavelength and direction **AND** emits the ***maximum*** amount radiation at a given temperature.
- It is an idealized body to serve as a standard against which the radiative properties of real surfaces may be compared.

Blackbody Radiation

12

- The amount of radiation emitted by a blackbody is given by **Planck's Law**:

$$E_{\lambda b} = \frac{2\pi h C_o^2}{\lambda^5 [\exp(h C_o / \lambda k T) - 1]}$$

where,

$k = 1.381 \times 10^{-23}$ J/K (Boltzmann's Constant)

- Planck's Law shows that the energy emitted from a blackbody does not depend on direction.
- Blackbody radiation is **diffuse**.

Blackbody Radiation

13

- From Planck's Law, we can find the wavelength at which the maximum radiation is emitted by a blackbody
- This is done by taking the derivative of $E_{\lambda b}$ and setting it to zero
- The result is called Wien's displacement law:

$$\lambda_{\max} T = 2897.8 \mu\text{m K}$$

Blackbody Radiation

14

- Integrating Planck's Law yields Stefan-Boltzmann's Equation:

$$E_b = \int_0^{\infty} E_{\lambda b} d\lambda = \sigma T^4$$

where,

$\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ (Stefan-Boltzmann Constant)

Radiation Emitted from a Real Surface

17

- A real surface does not emit as much energy as a blackbody.
- A real surface does not emit energy uniformly in all directions.
- The amount of energy emitted by a real surface is quantified by **emittance**.
- **Emittance** is the ratio of radiation emitted by a real surface to the radiation emitted by a blackbody at the same temperature.
- When the energy emitted in all directions and at all wavelengths is integrated, the result is the “**total hemispherical emittance**”

$$\varepsilon(T) = \frac{E(T)}{E_b(T)}$$

- Emittance ranges from 0 to 1.

- ***Irradiance*** is the rate at which radiant energy is incident on a surface per unit area of that surface (W/m^2).
- Some references refer to irradiance as “incident radiation”
- It is usually denoted with (G).
- Irradiance can be either:
 - **Absorbed**
 - **Reflected**
 - **Transmitted (if the medium is transparent)**

Irradiance

- The ratio of absorbed irradiance to total irradiance is called **absorptance** (α)
- The ratio of reflected irradiance to total irradiance is called **reflectance** (ρ)
- The ratio of transmitted irradiance to total irradiance is called **transmittance** (τ)

- Absorptance: $\alpha = \frac{\text{Absorbed radiation}}{\text{Irradiance}} = \frac{G_{\text{abs}}}{G}, \quad 0 \leq \alpha \leq 1$
- Reflectance: $\rho = \frac{\text{Reflected radiation}}{\text{Irradiance}} = \frac{G_{\text{ref}}}{G}, \quad 0 \leq \rho \leq 1$
- Transmittance: $\tau = \frac{\text{Transmitted radiation}}{\text{Irradiance}} = \frac{G_{\text{tr}}}{G}, \quad 0 \leq \tau \leq 1$
- $G_{\text{abs}} + G_{\text{ref}} + G_{\text{tr}} = G$
- $\alpha + \rho + \tau = 1$
- $\alpha + \rho = 1$ (for opaque surfaces)

- Radiation exchange between black bodies
- Radiation from a diffuse, gray surface

The total hemispherical emittance of a surface at temperature T is equal to its total hemispherical absorptance for radiation coming from a blackbody at the same temperature.

- $\varepsilon(T) = \alpha(T)$

- Electromagnetic radiation
- Thermal radiation
- Blackbody radiation
- Radiation emitted from a real surface
- Irradiance
- Kirchhoff's Law
- Diffuse and gray surface
- View factor
- Radiation exchange between black bodies
- Radiation from a diffuse, gray surface

- A **gray** surface is a surface whose ε and α are independent of wavelength.
- If the surface is diffuse and gray:

$$\varepsilon = \alpha$$

- In this case, the source of irradiation does not have to be a blackbody and the source's temperature does not have to be equal to the surface temperature

View Factor

27

- The **view factor** (F_{ij}) is the fraction of the radiation leaving surface i that strikes surface j directly
- The view factor ranges between 0 and 1.

EXAMPLE

- The view factor $F_{12} = 1$ since all the radiation leaving Surface 1 hits Surface 2.
- $F_{21} < 1$, since not all the radiation leaving Surface 2 will hit Surface 1.
- Some of the radiation leaving one part of Surface 2 will hit another part on Surface 2 itself.

The Reciprocity Relation

$$F_{j \rightarrow i} = F_{i \rightarrow j} \quad \text{when} \quad A_i = A_j$$

$$F_{j \rightarrow i} \neq F_{i \rightarrow j} \quad \text{when} \quad A_i \neq A_j$$

$$A_i F_{i \rightarrow j} = A_j F_{j \rightarrow i}$$

View Factor Relations

The Summation Rule

$$\sum_{j=1}^N F_{i \rightarrow j} = 1$$

- Diffuse and gray surface
- View factor
- Radiation exchange between black bodies
- Radiation from a diffuse, gray surface

- If Surface 1 and Surface 2 are blackbodies, the net radiation heat transfer from Surface 1 to Surface 2 is:

$$\dot{Q}_{1 \rightarrow 2} = \left(\begin{array}{c} \text{Radiation leaving} \\ \text{the entire surface 1} \\ \text{that strikes surface 2} \end{array} \right) - \left(\begin{array}{c} \text{Radiation leaving} \\ \text{the entire surface 2} \\ \text{that strikes surface 1} \end{array} \right)$$

$$= A_1 E_{b1} F_{1 \rightarrow 2} - A_2 E_{b2} F_{2 \rightarrow 1}$$

- The reciprocity relation asserts that: $A_1 F_{1 \rightarrow 2} = A_2 F_{2 \rightarrow 1}$
- Also: $E_b = \sigma T^4$
- Therefore,

$$\dot{Q}_{1 \rightarrow 2} = A_1 F_{1 \rightarrow 2} \sigma (T_1^4 - T_2^4)$$

- Electromagnetic radiation
- Thermal radiation
- Blackbody radiation
- Radiation emitted from a real surface
- Irradiance
- Kirchhoff's Law
- Diffuse and gray surface
- View factor
- Radiation exchange between black bodies
- Radiation from a diffuse, gray surface

- Radiation from a diffuse gray surface differs from radiation from a black body in two ways:
 - The radiation emitted is εE_b (instead of E_b)
 - The reflected radiation is ρG (instead of 0)
- The total radiation energy leaving a surface per unit time and per unit area is called **radiosity** (J).

Radiosity

$$J_i = \left(\begin{array}{c} \text{Radiation emitted} \\ \text{by surface } i \end{array} \right) + \left(\begin{array}{c} \text{Radiation reflected} \\ \text{by surface } i \end{array} \right)$$

$$J_i = \varepsilon_i E_b + \rho_i G_i$$

- But $\rho_i + \alpha_i = 1$
- For a diffuse gray surface, $\alpha_i = \varepsilon_i$
- Therefore: $\rho_i + \varepsilon_i = 1$

$$\rightarrow \rho_i = 1 - \varepsilon_i$$

$$\rightarrow J_i = \varepsilon_i E_b + (1 - \varepsilon_i) G_i$$

$$\rightarrow G_i = \frac{J_i - \varepsilon_i E_b}{(1 - \varepsilon_i)}$$

Net Rate of Radiation Heat Transfer from a Diffuse Gray Surface

39

$$\dot{Q}_i = \left(\text{Radiation leaving entire surface } i \right) - \left(\text{Radiation incident on entire surface } i \right)$$

$$= A_i (J_i - G_i)$$

$$= A_i \left(J_i - \frac{J_i - \varepsilon_i E_b}{1 - \varepsilon_i} \right)$$

$$= \frac{A_i \varepsilon_i}{1 - \varepsilon_i} (E_{bi} - J_i)$$

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1 - \varepsilon_1}{A_1 \varepsilon_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \varepsilon_2}{A_2 \varepsilon_2}} \quad (W)$$

- This is true for any two diffuse gray surfaces.

Example: Radiation from a horizontal solar collector to the sky at night

- The sky can be considered a blackbody at a temperature below ambient
