UNIT FOUR

SOLAR COLLECTORS

Flat Plate Collectors

- What are flat plate collectors?
- Types of flat plate collectors
- Applications of flat plate collectors
- Materials of construction and their properties
- Thermal analysis of flat plate collectors

What Are Flat Plate Collectors?

3

- A flat plate collector is a heat exchanger that uses solar irradiation to heat a working fluid.
- The working fluid is usually liquid or air.
- The collector is a black surface that is placed at a convenient path of the sun.
- In flat plate collectors there is no optical concentration of sunlight and they are generally stationary.
- The outlet temperature capability is below $100\text{ }^{\circ}\text{C}$

What Are Flat Plate Collectors?

4

- A typical flat plate collector is a metal box with a glass or plastic cover (called glazing) on top and a dark-colored absorber plate on the bottom.
- The sides and bottom of the collector are usually insulated to minimize heat loss.

Components of Flat Plate Collectors?

5

ABSORBER PLATE

- The plate is usually made of copper, steel, or plastic.
- The surface is covered with a black material of high absorptance.
- A selective coating can be used to maximize the absorptance of solar energy and minimizes the radiation emitted by plate.

Components of Flat Plate Collectors?

6

FLOW PASSAGES

- The flow passages carry the working fluid through the collector.
- If the working fluid is a liquid, the flow passage is usually a tube that is attached to, or is a part of absorber plate.
- If the working fluid is air, the flow passages can have different configurations.

Components of Flat Plate Collectors?

7

COVER PLATE (GLAZING)

- To reduce convective and radiative heat losses from the absorber, one or two transparent covers (glazing) are generally placed above the absorber plate.
- They usually be made from glass or plastic.

Components of Flat Plate Collectors?

8

INSULATION

- These are some materials such as fiberglass and they are placed at the back and sides of the collector to reduce heat losses.

Components of Flat Plate Collectors?

9

ENCLOSURE

- A box that encloses the collector to:
 - **Hold all the components together**
 - **Protect them from weather**
 - **Facilitate installation on a roof or appropriate frame.**

Energy Absorbed by a Flat Plate Collector

22

- The irradiation incident on a collector (G_t) is not all absorbed.
- Once the irradiation penetrates the glass cover, part of it is absorbed by the collector, but another part is reflected back diffusely to the glass cover.
- The glass cover then reflects diffusely to the absorber, and so on.

Energy Absorbed by a Flat Plate Collector

- The net energy absorbed by the collector can be expressed in terms of a quantity called $(\tau\alpha)$.
- Theoretically, the net energy absorbed by the collector per unit area is:

$$S = G_t (\tau\alpha)_{av}$$

Where $(\tau\alpha)_{av}$ is the average value of $(\tau\alpha)$

Energy Gain of a Flat Plate Collector

24

- The useful energy gain of a flat plate collector is given by:

$$Q_u = S \times A_c - Q_{\text{loss}}$$

- Q_{loss} can be due to energy loss through:

- **Top of the collector**
- **Bottom of collector**
- **Edges of collector**

- Q_{loss} can be expressed as: $Q_{\text{loss}} = U_L A_c (T_p - T_a)$

where,

- T_p : mean temperature of the absorber plate
- T_a : ambient temperature
- U_L : overall heat transfer coefficient based on collector area

- U_L consists of U_t (top), U_b (bottom), and U_e (edges)

U_t involves the calculation of:

- $h_{c,p-g}$: convective heat transfer coefficient between plate and glazing
- $h_{r,p-g}$: radiative heat transfer coefficient between plate and glazing
- $h_{c,g-a}$: convective heat transfer coefficient between glazing and ambient air
- $h_{r,g-a}$: radiative heat transfer coefficient between glazing and ambient air

- Calculations of all the components of U_t is complicated.

- A relatively simple alternative formula can be used:

$$U_t = \frac{1}{N_g} \frac{1}{\frac{C}{T_p} \left[\frac{T_p - T_a}{N_g + f} \right]^{0.33} + \frac{1}{h_w} + \frac{\sigma(T_p^2 + T_a^2)(T_p + T_a)}{\frac{1}{\varepsilon_p + 0.05N_g(1 - \varepsilon_p)} + \frac{2N_g + f - 1}{\varepsilon_g} - N_g}}$$

$$f = (1 - 0.04h_w + 0.0005h_w^2)(1 + 0.091N_g)$$

$$C = 365.9 (1 - 0.00883 \alpha + 0.0001298 \alpha^2)$$

$$h_w = \frac{8.6V^{0.6}}{L^{0.4}}$$

- U_b can be found from:

$$U_b = \frac{1}{\frac{t_b}{k_b} + \frac{1}{h_{c,b-a}}}$$

Where,

t_b = thickness of back insulation (m).

k_b = conductivity of back insulation (W/m-K).

$h_{c,b-a}$ = convection heat loss coefficient from back to ambient (W/m²-K).

- U_e can be found from:

$$U_e = \frac{1}{\frac{t_e}{k_e} + \frac{1}{h_{c,e-a}}}$$

Where,

t_e = thickness of edge insulation (m).

k_e = conductivity of edge insulation (W/m-K).

$h_{c,e-a}$ = convection heat loss coefficient from edge to ambient (W/m²-K).

Energy Gain of a Flat Plate Collector

30

- The useful energy gain of a flat plate collector is given by:

$$Q_u = S \times A_c - Q_{\text{loss}}$$

- Expanding all terms,

$$Q_u = A_c [G_t(\tau\alpha) - U_L(T_p - T_a)]$$

- The useful energy gained by the collector is transferred completely to the working fluid. Therefore,

$$Q_u = A_c [G_t(\tau\alpha) - U_L(T_p - T_a)] = \dot{m}c_p[T_o - T_i]$$

Where,

- T_i : fluid inlet temperature
- T_o : fluid outlet temperature

$$Q_u = A_c [G_t (\tau \alpha) - U_L (T_p - T_a)] = \dot{m} c_p [T_o - T_i]$$

- Calculating T_p accurately is difficult.
- It is more convenient to express Q_u in terms of the fluid temperatures.
- A useful definition is the heat removal factor (F_R):

$$F_R = \frac{\text{Actual output}}{\text{Output for plate temperature = Fluid inlet temperature}}$$

Heat Removal Factor

32

- By using the heat removal factor (F_R), the useful energy gain equation becomes:

$$Q_u = A_c F_R [G_t (\tau \alpha) - U_L (T_i - T_a)]$$

- F_R depends on many factors, and it can be found analytically.
- F_R can also be found experimentally.

Collector Efficiency

- Collector efficiency (η) is defined as the:
- η = useful energy gain / irradiation incident on the collector

$$\eta = \frac{Q_u}{G_t A_c}$$

- This equation can be expressed in terms of F_R :

$$\eta = F_R \left[(\tau\alpha) - \frac{U_L (T_i - T_a)}{G_t} \right]$$

- The efficiency equation can be rearranged as follows:

$$\eta = F_R(\tau\alpha) - F_R U_L \frac{T_i - T_a}{G_t}$$

- If changes in F_R and U_L are small, the equation above represents a straight line, where:
 - $(T_i - T_a) / G_t$ is the independent variable
 - η is the dependent variable
 - $F_R(\tau\alpha)$ is the intercept
 - $(- F_R U_L)$ is the slope

Collector Efficiency

$$\eta = \underbrace{F_R(\tau\alpha)}_{\text{Y-intercept}} - \underbrace{F_R U_L}_{\text{slope}} \frac{T_i - T_a}{G_t}$$
