Beer's- Lambert Law and Standard Curves

Spectrophotometer:

Spectrophotometer can be used to measure the amount of light absorbed or transmitted by a solution.

It consist of two parts: spectrometer and photometer.

By using the spectrophotometer, we can <u>quantitatively measure absorbance</u>, and this information can be used to determine the concentration of the absorbing molecule.

More concentrated solution will absorb more light and transmits less.

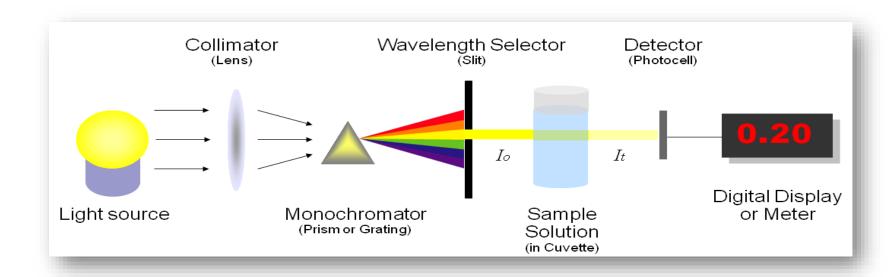

- **→**So:
- ➤ the <u>more</u> concentrated solution → high absorbance value.
- And Less concentrated solution \rightarrow less absorbance value.

Cont'

Wavelength in this instrument divided into:

- 1. Invisible range-ultraviolet- (from 100 to 360 nm).
- 2. Visible range (above 360 nm -700 nm).

Blank: contain everything <u>except</u> the compound to be measured.

Beer-Lambert law:

Principle:

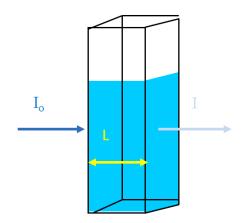

The absorption of light by a solution is described by the Beer-Lambert law as:

There is **linear** relationship between absorbance and concentration of an absorbing species.

$$\mathbf{A} = \mathbf{a}_{\mathbf{m}} \times \mathbf{c} \times \mathbf{l}$$

Where:

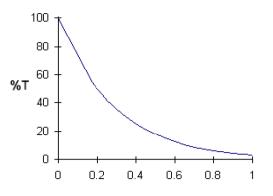

- \circ **A**= is the absorbance of the solution [Ab].
- \circ \mathbf{a}_{m} = the molar extinction(absorption) coefficient.
- \circ **l** = length of the light path through the solution.
- \circ **c** = concentration of the absorbing substance.

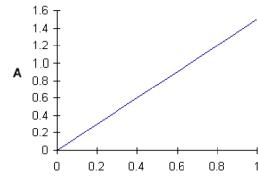

Cont'

From the law we observe:

- **1. Direct** relationship between C and A.
- **2. Direct** proportional between 1 and A.
- >If we plot absorbance against concentration, we get a **straight line**.
- >The linear relationship between concentration and absorbance is both simple and straightforward.
- → Which is why we prefer to express the Beer-Lambert law using absorbance as a measure of the concentration rather than %T (% transmittance).

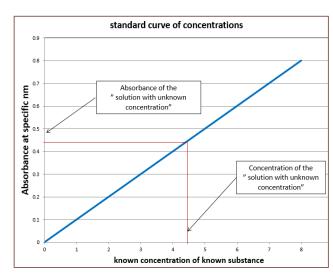

Standard curve for concentrations:

- → It is a graph that shows the relationship between different known concentrations of a substance and the absorbance at a specific wave length.
 - >Standard curve are most commonly <u>used to determine the concentration</u> of a substance, <u>using serial dilution of solutions (Standard solutions) of known concentrations.</u>

What is standard solutions:

- Is a solution containing a **precisely known concentration** of an element or a substance.
 - A series of known standard solutions can be Prepare by diluting the stock known solution.

(We should calculate the concentration of the diluted solution by the formula: $C_1 \times V_1 = C_2 \times V_2$)

Some points to consider:

- 1. The Ab of solution with "unknown concentration" must be **lower** than highest Ab value in standard Curve.
- → [the absorbance of solution with "unknown concentration", is within the rang of absorbance values of solution with "known concentration solutions"].
- 2. If your unknown sample had an absorbance higher the highest absorbance recorded by standard [out of the rang], how will you determine its concentration correctly?
- → Two choices:
- A. Increase the concentration of standard solution.
- B. Dilute the solution with "unknown concentration" \rightarrow measure the Ab after dilution \rightarrow then determine its concentration from the curve \rightarrow then multiply the value by Dilution factor.
- 3. If there is insufficient volume the light may pass over the solution instead of going through it.
- 4. Absorbance has no units.

Determining the unknown concentration of a solution by Known absorbance value

From standard curve

- The standard is constructed by plotting the absorbance values vs concentration and solving for the best straight line which is given in terms of: y = mx + b
- → where; y is absorbance, x concentration, b is the y intercept and m is the slope.
- Measure the absorbance of the "solution with unknown concentration" in order to determine the concentration.

Beer-Lambert law

- Using available information of any standard solution to determine the " ϵ ",
- Then using these information to get the unknown concentration using: $A = \varepsilon lc$
- Note: "\varepsilon" will changed when the weave length changed.

Practical Part

Objectives:

- □ To understand the concept of Beer-Lambert law and its application.
- Getting familiar with standard curve.
- Determination of an unknown concentration for a solution.

Method:

- □ You are provided by:
- Standard solution (Stock solution) of Copper Sulfate with 0.1 M [known concentration].
- 2. Solution with Unknown concentration "A".
- Solution with Unknown concentration "B".
- □ Set up 8 test tubes, as following table:

Tube	0.1M Copper Sulfate Standard Solution (ml)	Distal water (ml)	Solutions with unknown concentration (ml)
Blank	-	10 ml	-
A	2ml	8ml	-
В	4ml	6ml	-
С	6ml	4ml	-
D	8ml	2ml	-
E	1 Oml	-	-
Solution "A"	-	-	10 ml
Solution "B"	-	-	10 ml

- Mix the contents using the vortex.
- □ Measure the absorbance of each tube at 600 nm against the blank[.....].

Results:

- □ Calculate the concentrations of the series of known standard solutions.
- □ Plot the standard curve (Absorbance vs. Concentration), determine the concentration of unknown from graph.
- □ Determine the concentration of Solution "A" and "B".
- □ 1) from standard curve
- 2) using Beer-Lambert law

Tube	Absorbance at 600nm	Concentration M
Α		
В		
С		
D		
E		
Solution "A"		From the curve=
Solution "B"		From the curve=
