

### Coagulation

- Coagulation is a complex process by which <u>blood forms clots.</u>
- It is an important part of **hemostasis** (the cessation of blood loss from a damaged vessel).
- Disorders of coagulation can lead to an increased risk of bleeding (hemorrhage) or clotting (thrombosis).

### Hemostasis

- **Hemostasis** is a complex of homeostatic reactions, which result in <u>arrest of bleeding</u> from damaged blood vessels.
- Maintained in the body via three mechanisms:

#### 1. Vascular spasm

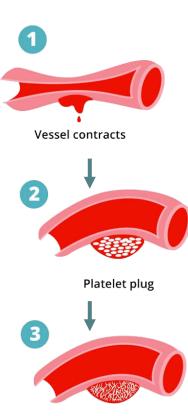

Damaged blood vessels constrict.

### 2. Platelet plug formation

Platelets adhere to damaged endothelium to form platelet plug (primary hemostasis).

#### 3. Blood Coagulation

Clots form upon the conversion of fibrinogen to Fibrin (secondary hemostasis).

Fibrin clot

## **Clotting Cascade**

• A **cascade** is a mechanism in which enzymes activate other enzymes sequentially usually leading to an amplification of an initial signal.

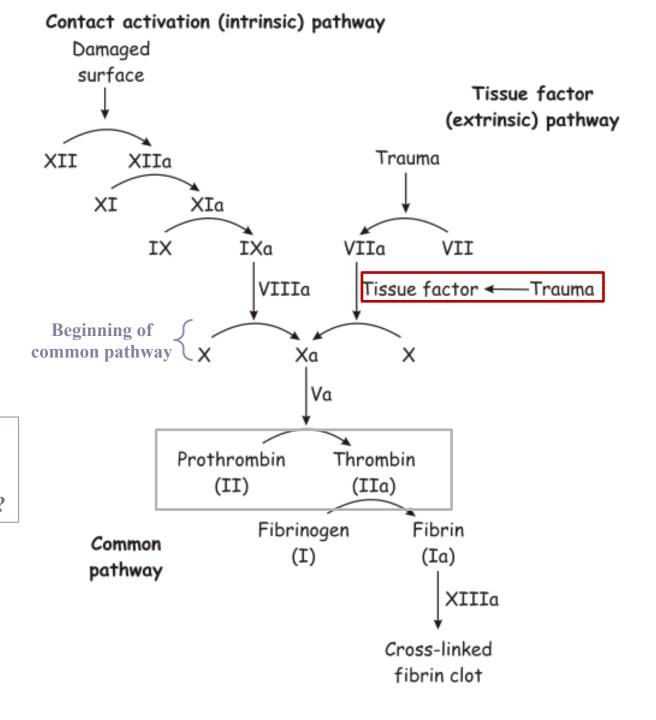

### **Pathways**

- 1. Extrinsic, which normally is triggered by trauma.
- 2. Intrinsic, which begins in the bloodstream and is triggered by internal damage to the wall of the vessel.
- Initially independent, then they converge on common pathway leading to the formation of a fibrin clot.
- Each of these pathways leads to the conversion of factor X (inactive) to factor Xa (active).

# **Clotting Cascade**

**Pause and Think why extrinsic pathway is completed** 

in seconds whereas intrinsic pathway takes few minutes?

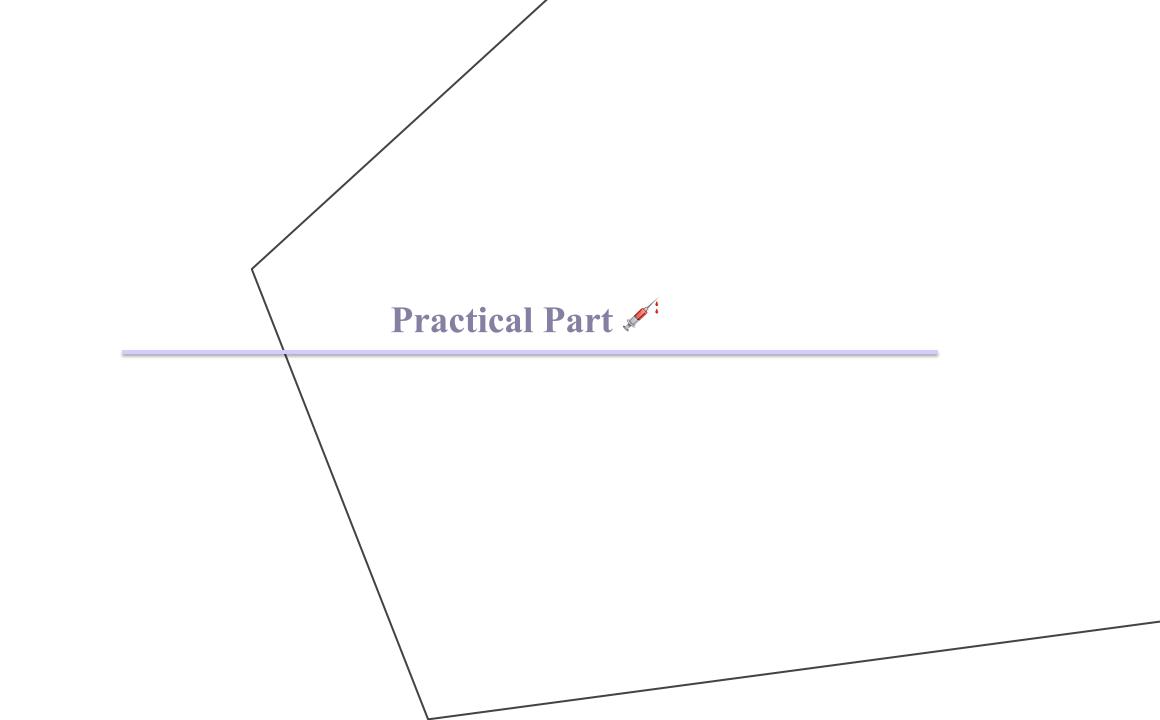

# What triggers extrinsic and intrinsic pathways?

#### **Extrinsic**

- Damage to tissue outside the blood vessel.
- This pathway acts to clot blood that has escaped from the vessel.

#### Intrinsic

- Damage to blood vessel wall.
- Coagulates the blood within the damaged vessel.
- Triggered by elements that lie within the blood itself.

## **Clotting Time**

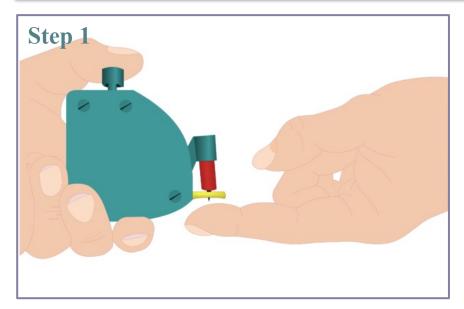

- Test for **intrinsic system.**
- Simple test but takes time and rarely done now.

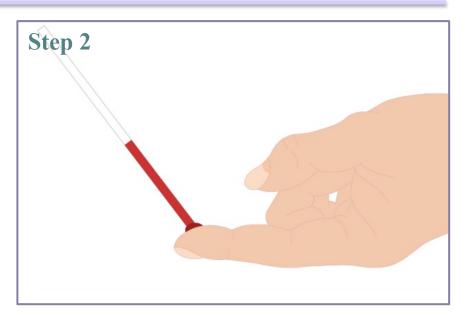

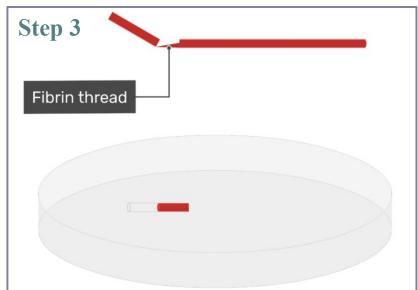

### **Method:**

- Venous blood is taken and placed on glass test tube at 37°C and it observed at time intervals until clotting occurs.
- Normal blood takes 5 10 min to clot.
- Longer periods → Coagulation defects (e.g. Hemophilia).

# **Clotting Time - Capillary Method**

## **Bleeding Time (BT)**

Provides assessment of <u>platelet count and function</u>.

### **Method:**

- It is determined by noting time at which blood coming out a small cut, no longer forms a spot on a
  - piece of filter paper placed in contact with cut surface.
- The normal range from **2-4 min.**

### **Prothrombin Time (PT)**

Measures effectiveness of the <u>extrinsic pathway</u>

#### **Method:**

- An excess of **tissue factor** and **Ca**<sup>2+</sup> ions are added to diluted plasma containing citrate (anticoagulant) and then the time taken for the mixture to clot is measured.
- Normal value  $\rightarrow$  10-15 secs
- **High PT**  $\rightarrow$  <u>low levels of thrombin</u>
- Results from liver disease due to deficiency of prothrombin, fibrinogen,
  V, VII and X factors.

### **Prothrombin Time [PT]**

- + Tissue Factor [TF]
- → Incubate at 37°C
- + Calcium
- → Record Clotting Time
